Problem 1: An Encryption Dilemma (5 points) [Codeforces]

By Andrew Tu

To protect the contents of your inbox from any snooping, you've designed an algorithm sure to befuddle anyone besides you. Specifically, you've taken all your current emails and inserted random characters all over the place. Where before you wrote: "Have a great day!", it now may read: "yHavje fa pglreat diayl!". To further throw off attackers, you've also added many completely gibberish emails to your inbox.

Unfortunately, in your haste to encrypt your inbox, you forgot to design a decryption mechanism, and now you're stuck trying to determine whether a given email is gibberish or an important conversation. Since you sign off each email with your Princeton email, you know that all legitimate emails had the word "princeton" before your encoding, and now have "princeton" as a subsequence, although possibly with random characters in between, before, or after letters. For any email that does not have "princeton" as a subsequence, you can be sure it's gibberish.

Using this criterion, determine for a given string whether it is an email or gibberish.

Princeton Computer Science Contest – Fall 2025

Input

The input is a single lowercase string s of length n consisting only of letters.

- $1 \leq n \leq 100$

Output

Print “email” if the string “princeton” is a subsequence of s and print “gibberish” otherwise.

Example 1

Input:

awpyiraigncjttaobnb

Output:

email

Explanation: “princeton” is a subsequence as highlighted in red, awpyir**aigncjtta**obnb.

Example 2

Input:

qpasriancea

Output:

gibberish

Explanation: Although “prince” is a subsequence, “princeton” is not.
